Exercise JavaScript part 3

Download the included zip which contains the necessary files to do this exercise. You can only edit the parts of the HTML that you are told to (don't edit anything else).

Important: Don't use innerHTML

Throughout this unit, we will develop the website for a second-hand marketplace application called Sanvipop. In this practical assignment, we will use a form to add products to a list.

There is a sample product already created on the HTML page. Based on it, you must create an **HTML template** containing the **div.col** element that will allow you to easily create a product **without** needing to use `createElement`, let alone `innerHTML`.

You must use what we have seen in class (e.g. use `addEventListener` for events, `append` to add to the DOM, etc.). Failure to do the practice according to the indicated instructions will result in a penalty.

New product form

You'll see in the HTML file there's a form. This form will add a new product with this data:

- **title** → Required (in the future we'll get them from a server)
- **description** → Required (in the future we'll get them from a server)
- **price** → Required. At least 0.01
- **category** → Required (in the future we'll get them from a server)
- **image** → Required (must be an image and less than 200kb)

When you select an image, it will show a preview inside the **img#imgPreview** element. In order to do that, transform the image to base64 format and put that in the `src` attribute.

The **img#imgPreview** element has a CSS class **"d-none"** which hides it. When the image is showing but the `src` attribute is empty or not correct, it will display a broken image icon in many browsers. You should remove this class before assigning the base64 image to this element, and add it again when the selected file is not correct.

Also, using the Constraint Validation API, verify that the selected file is an image (check that **file.type** starts with "image"), and it doesn't weight more than 200KB.

Submitting the form

When the user submits the form, do the following:

- Validate the form using the Constraint Validation API. If it's not valid, don't continue.
- If everything is correct, add the new product to the HTML document, and reset the form (also hide the preview image).
 - Use the template you must create in the HTML file (remember to clone it) and fill

- it with the form's data. Do this in a separate function.
- Create an object with all the product's data and pass it to the function mentioned above.
 - Transform the price to currency (in € and english) using the Intl API.
 - Append the card to the DOM (inside the **div#productsContainer** element).
 - Add the click event to the delete button inside the card (button.btn-delete). When this button is clicked, it will remove the card from the DOM.

Important: You must run this exercise using a local web server. The easiest way would be using VS Code extension: **Live Server**.
